## COMPLETE SPECIFICATION

### Improved vertical take-off aircraft

We, ROLLS-ROYCE LIMITED, a British company of Nightingale Road, Derby, Derbyshire, do hereby declare the invention for which we pray that a patent may be granted to us, and the method by which it is to be performed to be particularly described in and by the following statement:-

This invention concerns vertical take-off aircraft.

Vertical take-off aircraft are provided with engines (hereinafter referred to as lifting engines) which produce lift forces on the aircraft. Independently of lift forces which are generated aerodynamically by forward flight of the aircraft. The lifting engines are employed to effect take-off and descent of the aircraft, forward propulsion engines being employed to effect normal forward flight of the aircraft.

Thus, at take-off of the aircraft, the lifting engines are employed to lift the aircraft to a suitable altitude, after which the forward propulsion engines are brought into operation; when sufficient lift forces are generated aerodynamically by the forward flight of the aircraft the lifting engines are made inoperative.

Accordingly it may be desirable to arrange that when, on take-off, the aircraft has reached a suitable altitude, the propulsive gases discharged by the lifting engines shall be so directed as to provide a forward component of thrust on the aircraft so as to assist the forward propulsion engines. Similarly, immediately prior to descent, it may be desired that the propulsive gases discharged by the lifting engines shall be so directed as to provide a rearward component of thrust on the aircraft so as to reduce the forward speed of the

aircraft, after which descent may be effected.

It is therefore the object of the present invention to provide a vertical take-off aircraft with means whereby the above-mentioned forward or rearward components of thrust may be produced.

According to the present invention in its broadest aspect there is provided a vertical take-off aircraft having at least one lifting engine, which is mounted to discharge propulsive gases downwardly, and at least one gas deflector member mounted below said engine, the gas deflector member being maintainable in a position in which it serves to deflect the downwardly directed propulsive gases away from the vertical so as to produce a forward or rearward component of thrust on said aircraft, means being provided for hindering or preventing the flow of said gases transversely of the aircraft whilst said gases are being deflected by said gas deflector member.

In one embodiment of the present invention there is provided a vertical take-off aircraft having at least one lifting engine which is arranged to discharge propulsive gases downwardly through an aperture in the aircraft structure, at least one flap member being provided which is movable into three positions, namely a closed position in which the aperture is sealed, a fully open position in which the propulsive gases may be vertically directed, and an inclined position in which the flap member serves to deflect the propulsive gases away from the vertical so as to produce a forward or rearward component of thrust on said aircraft, means being provided for hindering or preventing the flow of

said gases transversely of the aircraft whilst said gases are being deflected by said flap members.

Preferably there are a plurality of flap members corresponding respectively to a plurality of engines, the arrangement being such that, when the flap members are in the closed position, they seal against each other and against the adjacent outer surfaces of the aircraft. Preferably there are at least four engines.

The said means may be constituted by webs provided on the flap member or members.

The invention is illustrated, merely by way of example, in the drawings of which Figures 1-4 accompanied the provisional specification and Figures 5 and 6 accompany the present specification. In said drawings:-

Figure 1 is an elevation of a vertical take-off aircraft according to the present invention, the structure of the aircraft being partly broken away to illustrate the lifting engines of the aircraft.

Figure 2 is a sectional elevation of a part of the aircraft shown in

Figure 1, which is a broken away section on the line 3-3 of Figure 4, illustrates the fully open position of the flap members which are disposed below the lifting engines of the aircraft according to the invention.

Figure 4 is a broken away section of the line 4-4 of Figure 3.

Figure 5 is a broken away sectional elevation showing part of a modified vertical take-off aircraft according to the invention, and

Figure 6 is a perspective view of a flap member forming part of the construction of Figure 5.

Referring to Figures 1-4 of the drawings, a vertical take-off aircraft 10 is provided with six gas-turbine jet-reaction lifting engines 11 arranged in an engine bay 12. Alternatively the engines 11 could, if desired, be constituted by turbo-driven fans.

The upper end of the bay 12 is adapted to be opened and closed by pivotally mounted flap members 13 each of which is movable between the full line position shown in Figure 2, in which the flap members 13 serve collectively to close the upper end of the bay 12, and the dotted line position shown in Figure 2, in which the flap members 13 are fully open. In the full line, or closed position, the flap members 13 are disposed in the

general aerodynamic profile of the aircraft and seal against each other and with the adjacent aircraft surfaces so as to prevent any ingress of air into the bay 12. The flap members 13 may also be disposed in forwardly inclined positions (not shown) so that, on forward flight of the aircraft, they serve to deflect ambient air into the intakes of the lifting engines 11, such deflection of the ambient air assisting the operation of these engines, which would be tilted forward.

The lower end of the bay 12 is adapted to be opened and closed by three pivotally mounted flap members 14 which are adapted to be set in a closed position, a forwardly inclined position and any position between the closed and forwardly inclined position.

In the closed position, shown in full lines in Figure 2, the flap members 14 are disposed in the general aerodynamic profile of the aircraft and seal against each other and against the adjacent aircraft surfaces so as to prevent any ingress of air into the bay 12.

An inclined position of the flap members 14 is shown in dotted lines in Figure 2 in which the flap members 14 serve to deflect the propulsive gases from the lifting engines 11 away from the vertical so as to produce a forward component of thrust on the aircraft. It will readily be appreciated that the flap members 14 may, if so desired, be inclined forward so that they deflect the propulsive gases forwardly whereby they produce a rearward component of thrust on the aircraft. The rear engine gas flow, in this case, does not contribute to the "braking" effect.

In the fully open position shown in Figures 3 and 4, the flap members 14 are vertically disposed so that the propulsive gases from the engines 11 will be vertically downwardly directed.

It is preferably arranged that the intake flap members 13 and the exhaust flap members 14 are progressively opened or closed at a rate dependent upon the forward speed of the aircraft, for example the arrangement may be that the flaps will be only partially open when the forward speed of the aircraft is relatively high, the ram effect on the air being sufficient for operation of the lifting engines; the flaps will, however, be vertical when the forward speed of the aircraft falls to approximately zero, when there will be no ram effect to force the air through the engine intakes.

1,000,000

The flap member 14 illustrated in Figure 4 is shown as being rotatable by a control lever 15 so that it can be disposed in each of the positions referred to above. The showing of the control lever 15 is, of course, purely diagrammatic. In practice it could be arranged that all the flap members 14 are moved by means of a common control operable from the pilot's cabin, such control comprising means for maintaining the flap members 14 in a selected position.

Each flap member 14 is provided with a plurality of longitudinally extending, spaced apart webs 16. The webs 16, in addition to strengthening the flap members, serve to inhibit cross flow of propulsive gases from the engines 11, that is to say flow of the propulsive gases transversely of the aircraft. It is desirable to prevent such cross flows since these can cause yawing of the aircraft.

Since both the flap members 13 and the flap members 14, when in their closed positions, seal one with another and with the adjacent aircraft surfaces, it is unnecessary to provide additional members to close the upper and lower ends of the bay 12.

In Figures 5 and 6 there is shown an alternative construction in which the flap members 14 are replaced by flap members 17. The flap members 17 have spaced side walls 18 between which extend an inner curved deflector 19 and an outer curved deflector 20, the deflectors 19, 20 being spaced from and parallel to each other.

One of the ends 21 of each flap member 17 is smoothly curved, the deflector 19 constituting a smooth continuation of the end 21. The end 21 has a hole 22 therethrough which receives a pivot pin 23, the pin 23 being carried by a bar 24 mounted (by means not shown) within the bay 12.

The flap members 17 are movable in the same way as the flap members 14 so as to deflect the propulsive gases from the lifting engines 11. The provision of the two spaced, curved deflectors 19, 20 assists in the smooth deflection of the propulsive gases into the desired direction.

#### WHAT WE CLAIM IS:-

1. A vertical take-off aircraft having at least one lifting engine, which is mounted to discharge propulsive gases downwardly, and at least one gas deflector member mounted below said engine, the gas deflector member being maintainable in a position in which it serves to deflect the

downwardly directed propulsive gases away from the vertical so as to produce a forward or rearward component of thrust on said aircraft, means being provided for hindering or preventing the flow of said gases transversely of the aircraft whilst said gases are being deflected by said gas deflector member.

2. A vertical take-off aircraft having at least one lifting engine, which is arranged to discharge propulsive gases downwardly through an aperture in the aircraft structure, at least one flap member being provided which is movable into three positions, namely a closed position in which the aperture is sealed, a fully open position in which the propulsive gases may be vertically directed, and an inclined position in which the flap member serves to deflect the propulsive gases away from the vertical so as to produce a forward or rearward component of thrust on said aircraft, means being provided for hindering or preventing the flow of said gases transversely of the aircraft whilst said gases are being deflected by said flap member.

3. An aircraft as claimed in Claim 2 in which there are a plurality of flap members corresponding respectively to a plurality of engines, the arrangement being such that, when the flap members are in the closed position, they seal against each other and against the adjacent outer surfaces of the aircraft.

4. An aircraft as claimed in Claim 2 or 3 in which there are at least four engines.

5. An aircraft as claimed in any of Claims 2 to 4 in which the said means are constituted by webs provided on the flap member or members.

6. An aircraft as claimed in any of Claims 2-5 in which each of the flap members comprises at least one curved deflector member for deflecting the said propulsive gases.

7. An aircraft as claimed in Claim 6 in which each flap member is provided with two spaced curved deflectors.

8. An aircraft as claimed in any of Claims 2-7 in which each of the flap members is pivotally mounted at the lower end of an engine bay.

9. An aircraft as claimed in any of Claims 2-8 in which the upper end of the bay is provided with flap members which are movable between an open position and a position in which they collectively close the said upper end.

10. An aircraft as claimed in

Claim 9 in which the flap members at the upper end of the bay are positionable in an inclined position such that, on forward flight of the aircraft, they serve to deflect ambient air into the intake or intakes of any engines in said bay.

11. An aircraft substantially as described with reference to and as shown in Figures 1-4 of the

## PROVISIONAL SPECIFICATION

No. 728 A. D. 1959

### Improved vertical take-off aircraft

We, ROLLS-ROYCE LIMITED, a British Company, of Nightingale Road, Derby, Derbyshire, do hereby declare this invention to be described in the following statement:-

This invention concerns vertical take-off aircraft.

Vertical take-off aircraft are provided with engines (hereinafter referred to as lifting engines) which produce lift forces on the aircraft independently of lift forces which are generated aerodynamically by forward flight of the aircraft. The lifting engines are employed to effect take-off and descent of the aircraft, forward propulsion engines being employed to effect normal forward flight of the aircraft.

Thus, at take-off of the aircraft, the lifting engines are employed to lift the aircraft to a suitable altitude, after which the forward propulsion engines are brought into operation; when sufficient lift forces are generated aerodynamically by the forward flight of the aircraft the lifting engines are made inoperative.

Accordingly it may be desirable to arrange that when, on take-off, the aircraft has reached a suitable altitude, the propulsive gases dis-

charged by the lifting engines shall be so directed as to provide a forward component of thrust on the aircraft so as to assist the forward propulsion engines. Similarly, immediately prior to descent, it may be desired that the propulsive gases discharged by the lifting engines shall be so directed as to provide a rearward component of thrust on the aircraft so as to reduce the forward speed of the aircraft, after which descent may be effected. It is therefore the object of the present invention to provide a vertical take-off aircraft with means whereby the above-mentioned forward or rearward

components of thrust may be produced. According to the present invention in its broadest aspect there is provided a vertical take-off aircraft having at least one lifting engine, which is mounted to discharge propulsive gases downwardly, and at least one gas deflector member mounted below said engine, the gas deflector member being maintainable in a position in which it serves to deflect the downwardly directed propulsive gases away from the vertical so as to produce a forward or rearward component of thrust on said aircraft.

In one form, the present invention comprises a vertical take-off aircraft having at least one lifting engine which is arranged to discharge propulsive gases downwardly through an aperture in the aircraft structure, at least one flap member being provided which is movable into three positions, namely a closed position in which the aperture is sealed, a fully open position in which the propulsive gases may be vertically directed, and an inclined position in which the flap member serves to deflect the propulsive gases away from the vertical so as to produce a forward or rearward component of thrust on said aircraft.

Preferably there are a plurality of flap members corresponding respectively to a plurality of engines, the arrangement being such that, when the flap members are in the closed position, they seal against each other and against the adjacent outer surfaces of the aircraft. Preferably there are at least four engines.

Means are preferably provided for hindering or preventing flow of propulsive gases transversely of the aircraft. Thus the said means may be constituted by webs provided on the flap member or members.

The invention is illustrated, merely

provisional specification or Figures 5 and 6 of the accompanying drawings.

from which copies may be obtained.

by way of example, in the accompanying drawings in which:-

Figure 1 is an elevation of a vertical take-off aircraft according to the present invention, the structure of the aircraft being partly broken away to illustrate the lifting engines of the aircraft.

Figure 2 is a sectional elevation of a part of the aircraft shown in Figure 1.

Figure 3, which is a broken away section on the line 3-3 of Figure 4, illustrates the fully open position of the flap members which are disposed below the lifting engines of the aircraft according to the invention, and Figure 4 is a broken away section on the line 4-4 of Figure 3.

Referring to the drawings, a vertical take-off aircraft 10 is provided with six gas-turbine jet-reaction engines 11. Alternatively the engines 11 could, if desired, be constituted by turbo-driven fans. The upper end of the bay 12 is adapted to be opened and closed by pivotally mounted flap members 13 each of which is movable between the full line position shown in Figure 2, in which the flap members 13 serve collectively to close the upper end of the bay 12, and the dotted line position shown in Figure 2, in which the flap members 13 are fully open. In the full line, or closed position, the flap members 13 are disposed in the general aerodynamic profile of the aircraft and seal against each other and with the adjacent aircraft surfaces so as to prevent any ingress of air into the bay 12. The flap members 13 may also be disposed in forwardly inclined positions (not shown) so that, on forward flight of the aircraft, they serve to deflect ambient air into the intakes of the lifting engines 11, such deflection of the ambient air assisting starting of these engines, which would be tilted forward.

The lower end of the bay 12 is adapted to be opened and closed by three pivotally mounted flap members 14 which are adapted to be set in a closed position, a forwardly inclined position and any position between the closed and forwardly inclined position. In the closed position, shown in full lines in Figure 2, the flap members 14 are disposed in the general aerodynamic profile of the aircraft and seal against each other and against the adjacent aircraft surfaces so as to prevent any ingress of air into

the bay 12.

An inclined position of the flap members 14 is shown in dotted lines in Figure 2 in which the flap members 14 serve to deflect the propulsive gases from the lifting engines 11 away from the vertical so as to produce a forward component of thrust on the aircraft. It will readily be appreciated that the flap members 14 may, if so desired, be inclined forwards so that they deflect the propulsive gases forwardly whereby to produce a rearward component of thrust on the aircraft. The rear engine gas flow, in this case, does not contribute to the "braking" effect.

In the fully open position shown in Figures 3 and 4, the flap members 14 are vertically disposed so that the propulsive gases from the engines 11 will be vertically downwardly directed.

It is preferably arranged that the intake flap members 13 and the exhaust flap members 14 are progressively opened or closed at a rate dependent upon the forward speed of the aircraft, for example the arrangement may be that the flaps will be only partially open when the forward speed of the aircraft is relatively high, the ram effect on the air being sufficient for operation of the lifting engines; the flaps will, however, be vertical when the forward speed of the aircraft falls to approximately zero, when there will be no ram effect to force the air through the engine intakes.

The flap member 14 illustrated in Figure 4 is shown as being rotatable by a control lever 15 so that it can be disposed in each of the positions referred to above. The showing of the control lever 15 is, of course, purely diagrammatic. In practice it could be arranged that all the flap members 14 are moved by means of a common control operable from the pilot's cabin, such control comprising means for maintaining the flap members 14 in a selected position.

Each flap member 14 is provided with a plurality of longitudinally extending, spaced apart webs 16. The webs 16, in addition to strengthening the flap members, serve to inhibit cross flow of propulsive gases from the engines 11, that is to say flow of the propulsive gases transversely of the aircraft. It is desirable to prevent such cross flows since these can cause yawing of the aircraft.
